Final Project Proposal

Final Project Proposal: Online Gaming Storefront

Introduction
For my final project, I am proposing to develop a database to mimic an online storefront/library management service. This project is modeled after other platforms like Steam or the Epic Games Store. The system will store information about users, games, the games played by users, and developers of the games.

Types of Users
There are four main user types associated with this system: Players are the main user type. Players are able to purchase games to play and have stats like playtime and achievements be recorded in. Developers are users who create games and publish them into the storefront. Developers in this implementation are not active users, they are mainly used to track games by developer and view ratings across all titles a developer worked on. Platform admins are a required user, as this user type manages the users on the system.

Questions the System can Answer
There are numerous questions this system should be able to answer.

1. Which games are owned by which players?
2. How much as one user spent on games?
3. Which games have been purchased the most?
4. Which developers have made the most liked games?

Major Entities in the System

- Users - Stores player account information
- Games - Stores game information
- Developers - Stores information about game developers.
- Library - A record of all games a user has purchased, and statistics about game purchases/orders.
- LibraryGame (Junction for Library and Game)
- Orders - A record of all orders placed, which user placed them, and the games within that order.
- OrderGame (Junction for Orders and Games)
- Achievements Stores achievement information associated with games.
- UserAchievement (Junction for Users and Achievements)
- GameDeveloper (Junction for Games and Developers)
